

EXERCISE: USE A HOOK

► **Replace the "when passed a single argument --foo" with this:**

```
► describe('when passed a single argument --foo', function() {  
  it('should return an object having property foo: true', function () {  
    assert.strictEqual(parse(['--foo']).foo, true);  
  });  
  
  it('should return an object having no positional arguments', function () {  
    assert.deepStrictEqual(parse(['--foo'])._, []);  
  });  
});
```

► Remember, to run tests:

► `npm test`

EXERCISE: USE A HOOK (CONT'D)

- ▶ **Add a “before each” hook to the “when passed a single argument --foo” which prepares the scenario for the two tests**
- ▶ Hint: the *only* function call in each *test body* will be the given *assert* function call
- ▶ Hint: declare a variable in the *suite body* and define the variable in the *hook body*
